The Relational Algebra

Chapter Outline

- Relational Algebra
 - Unary Relational Operations
 - Relational Algebra Operations From Set Theory
 - Binary Relational Operations
 - Additional Relational Operations
 - Examples of Queries in Relational Algebra

Relational Algebra Overview

- Relational algebra is the basic set of operations for the relational model
- These operations enable a user to specify basic retrieval requests (or queries)
- The result of an operation is a new relation, which may have been formed from one or more input relations
 - This property makes the algebra "closed" (all objects in relational algebra are relations)

Relational Algebra Overview (continued)

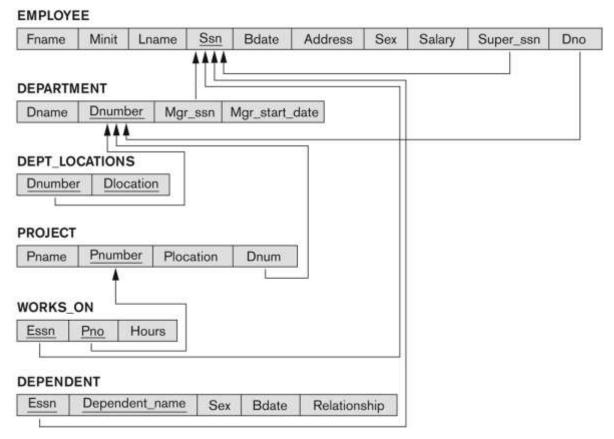

- The algebra operations thus produce new relations
 - These can be further manipulated using operations of the same algebra
- A sequence of relational algebra operations forms a relational algebra expression
 - The result of a relational algebra expression is also a relation that represents the result of a database query (or retrieval request)

Relational Algebra Overview

- Relational Algebra consists of several groups of operations
 - Unary Relational Operations
 - SELECT (symbol: σ (sigma))
 - PROJECT (symbol: π (pi))
 - RENAME (symbol: ρ (rho))
 - Relational Algebra Operations From Set Theory
 - UNION (∪), INTERSECTION (∩), DIFFERENCE (or MINUS,)
 - CARTESIAN PRODUCT (x)
 - Binary Relational Operations
 - JOIN (several variations of JOIN exist)
 - DIVISION
 - Additional Relational Operations
 - OUTER JOINS, OUTER UNION
 - AGGREGATE FUNCTIONS (These compute summary of information: for example, SUM, COUNT, AVG, MIN, MAX)

Database State for COMPANY

All examples discussed below refer to the COMPANY database shown here.
 Figure 5.7
Referential integrity constraints displayed on the COMPANY relational database schema.

Unary Relational Operations: SELECT

- The SELECT operation (denoted by σ (sigma)) is used to select a subset of the tuples from a relation based on a selection condition.
 - The selection condition acts as a filter
 - Keeps only those tuples that satisfy the qualifying condition
 - Tuples satisfying the condition are selected whereas the other tuples are discarded (filtered out)
- Examples:
 - Select the EMPLOYEE tuples whose department number is 4:

$$\sigma_{DNO=4}$$
 (EMPLOYEE)

Select the employee tuples whose salary is greater than \$30,000:

Unary Relational Operations: SELECT

- In general, the select operation is denoted by
 - $\sigma_{\text{selection condition}}(R)$ where
 - the symbol σ (sigma) is used to denote the select operator
 - the selection condition is a Boolean (conditional)
 expression specified on the attributes of relation R
 - tuples that make the condition true are selected
 - appear in the result of the operation
 - tuples that make the condition false are filtered out
 - discarded from the result of the operation

Unary Relational Operations: SELECT (contd.)

- SELECT Operation Properties
 - The SELECT operation $\sigma_{\text{selection condition}}(R)$ produces a relation S that has the same schema (same attributes) as R
 - SELECT σ is commutative:
 - $\sigma_{\text{condition}1>}(\sigma_{\text{condition}2>}(R)) = \sigma_{\text{condition}2>}(\sigma_{\text{condition}1>}(R))$
 - Because of commutativity property, a cascade (sequence) of SELECT operations may be applied in any order:
 - $\quad \sigma_{\text{cond1}>}(\sigma_{\text{cond2}>}(\sigma_{\text{cond3}>}(R)) = \sigma_{\text{cond2}>}(\sigma_{\text{cond3}>}(\sigma_{\text{cond1}>}(R)))$
 - A cascade of SELECT operations may be replaced by a single selection with a conjunction of all the conditions:
 - $\sigma_{<\text{cond1>}}(\sigma_{<\text{cond2>}}(R)) = \sigma_{<\text{cond1>}}(R) = \sigma_{<\text{cond2>}}(R)$
 - The number of tuples in the result of a SELECT is less than (or equal to) the number of tuples in the input relation R

The following query results refer to this database state

Figure 5.6

One possible database state for the COMPANY relational database schema.

Unary Relational Operations: PROJECT

- PROJECT Operation is denoted by π (pi)
- This operation keeps certain columns (attributes) from a relation and discards the other columns.
 - PROJECT creates a vertical partitioning
 - The list of specified columns (attributes) is kept in each tuple
 - The other attributes in each tuple are discarded
- Example: To list each employee's first and last name and salary, the following is used:

 $\pi_{\text{LNAME, FNAME,SALARY}}(\text{EMPLOYEE})$

Unary Relational Operations: PROJECT (cont.)

The general form of the *project* operation is:

$$\pi_{\text{}}(R)$$

- ${f \pi}$ (pi) is the symbol used to represent the *project* operation
- <attribute list> is the desired list of attributes from relation R.
- The project operation removes any duplicate tuples
 - This is because the result of the project operation must be a set of tuples
 - Mathematical sets do not allow duplicate elements.

Unary Relational Operations: PROJECT (contd.)

PROJECT Operation Properties

- The number of tuples in the result of projection π_{<list>}(R) is always less or equal to the number of tuples in R
 - If the list of attributes includes a key of R, then the number of tuples in the result of PROJECT is equal to the number of tuples in R
- PROJECT is not commutative
 - $\pi_{\text{<list1>}}$ ($\pi_{\text{<list2>}}$ (R)) = $\pi_{\text{<list1>}}$ (R) as long as <list2> contains the attributes in <list1>

Examples of applying SELECT and PROJECT operations

Relational Algebra Expressions

- We may want to apply several relational algebra operations one after the other
 - Either we can write the operations as a single relational algebra expression by nesting the operations, or
 - We can apply one operation at a time and create intermediate result relations.
- In the latter case, we must give names to the relations that hold the intermediate results.

Single expression versus sequence of relational operations (Example)

- To retrieve the first name, last name, and salary of all employees who work in department number 5, we must apply a select and a project operation
- We can write a single relational algebra expression as follows:
 - $\pi_{\text{FNAME, LNAME, SALARY}}(\sigma_{\text{DNO}=5}(\text{EMPLOYEE}))$
- OR We can explicitly show the sequence of operations, giving a name to each intermediate relation:
 - DEP5_EMPS $\leftarrow \sigma_{DNO=5}(EMPLOYEE)$
 - RESULT $\leftarrow \pi$ FNAME, LNAME, SALARY (DEP5_EMPS)

Unary Relational Operations: RENAME

- The RENAME operator is denoted by ρ (rho)
- In some cases, we may want to rename the attributes of a relation or the relation name or both
 - Useful when a query requires multiple operations
 - Necessary in some cases (see JOIN operation later)

Unary Relational Operations: RENAME (contd.)

- The general RENAME operation ρ can be expressed by any of the following forms:
 - ρ_{S (B1, B2, ..., Bn)}(R) changes both:
 - the relation name to S, and
 - the column (attribute) names to B1, B1,Bn
 - $\rho_S(R)$ changes:
 - the relation name only to S
 - ρ_(B1, B2, ..., Bn)(R) changes:
 - the column (attribute) names only to B1, B1,Bn

Unary Relational Operations: RENAME (contd.)

- For convenience, we also use a shorthand for renaming attributes in an intermediate relation:
 - If we write:
 - RESULT $\leftarrow \pi_{\text{FNAME, LNAME, SALARY}}$ (DEP5_EMPS)
 - RESULT will have the same attribute names as DEP5_EMPS (same attributes as EMPLOYEE)
 - If we write:
 - RESULT (F, M, L, S, B, A, SX, SAL, SU, DNO) $\leftarrow \pi_{\text{FNAME, LNAME, SALARY}}$ (DEP5_EMPS)
 - The 10 attributes of DEP5_EMPS are renamed to F, M, L, S, B, A, SX, SAL, SU, DNO, respectively

Relational Algebra Operations from Set Theory: UNION

UNION Operation

- Binary operation, denoted by ∪
- The result of R ∪ S, is a relation that includes all tuples that are either in R or in S or in both R and S
- Duplicate tuples are eliminated
- The two operand relations R and S must be "type compatible" (or UNION compatible)
 - R and S must have same number of attributes
 - Each pair of corresponding attributes must be type compatible (have same or compatible domains)

Relational Algebra Operations from Set Theory: UNION

Example:

- To retrieve the social security numbers of all employees who either work in department 5 (RESULT1 below) or directly supervise an employee who works in department 5 (RESULT2 below)
- We can use the UNION operation as follows:

```
DEP5_EMPS \leftarrow \sigma_{\text{DNO}=5} (EMPLOYEE)

RESULT1 \leftarrow \pi_{\text{SSN}}(DEP5_EMPS)

RESULT2(SSN) \leftarrow \pi_{\text{SUPERSSN}}(DEP5_EMPS)

RESULT \leftarrow RESULT1 \cup RESULT2
```

 The union operation produces the tuples that are in either RESULT1 or RESULT2 or both

Relational Algebra Operations from Set Theory

- Type Compatibility of operands is required for the binary set operation UNION ∪, (also for INTERSECTION ∩, and SET DIFFERENCE –, see next slides)
- R1(A1, A2, ..., An) and R2(B1, B2, ..., Bn) are type compatible if:
 - they have the same number of attributes, and
 - the domains of corresponding attributes are type compatible (i.e. dom(Ai)=dom(Bi) for i=1, 2, ..., n).
- The resulting relation for R1∪R2 (also for R1∩R2, or R1−R2, see next slides) has the same attribute names as the first operand relation R1 (by convention)

Relational Algebra Operations from Set Theory: INTERSECTION

- INTERSECTION is denoted by
- The result of the operation R ∩ S, is a relation that includes all tuples that are in both R and S
 - The attribute names in the result will be the same as the attribute names in R
- The two operand relations R and S must be "type compatible"

Relational Algebra Operations from Set Theory: SET DIFFERENCE (cont.)

- SET DIFFERENCE (also called MINUS or EXCEPT) is denoted by –
- The result of R S, is a relation that includes all tuples that are in R but not in S
 - The attribute names in the result will be the same as the attribute names in R
- The two operand relations R and S must be "type compatible"

Figure 6.4

The set operations UNION, INTERSECTION, and MINUS. (a) Two union-compatible relations. (b) STUDENT ∪ INSTRUCTOR. (c) STUDENT ∩ INSTRUCTOR. (d) STUDENT − INSTRUCTOR. (e) INSTRUCTOR − STUDENT.

Some properties of UNION, INTERSECT, and DIFFERENCE

- Notice that both union and intersection are commutative operations; that is
 - $R \cup S = S \cup R$, and $R \cap S = S \cap R$
- Both union and intersection can be treated as n-ary operations applicable to any number of relations as both are associative operations; that is
 - $R \cup (S \cup T) = (R \cup S) \cup T$
 - $(R \cap S) \cap T = R \cap (S \cap T)$
- The minus operation is not commutative; that is, in general
 - \blacksquare R S \neq S R

Relational Algebra Operations from Set Theory: CARTESIAN PRODUCT

- CARTESIAN (or CROSS) PRODUCT Operation
 - This operation is used to combine tuples from two relations in a combinatorial fashion.
 - Denoted by R(A1, A2, . . ., An) x S(B1, B2, . . ., Bm)
 - Result is a relation Q with degree n + m attributes:
 - Q(A1, A2, ..., An, B1, B2, ..., Bm), in that order.
 - The resulting relation state has one tuple for each combination of tuples—one from R and one from S.
 - Hence, if R has n_R tuples (denoted as |R| = n_R), and S has n_S tuples, then R x S will have n_R * n_S tuples.
 - The two operands do NOT have to be "type compatible"

Join Operation

- Join is a commonly used sequence of operators
 - Take the Cartesian product of two relations
 - Select only related tuples
 - (Possibly) eliminate duplicate columns

Join Example

$$R1 \leftarrow R \times S$$

$$R2 \leftarrow \sigma_{dcode = code}(R1)$$

Result
$$\leftarrow \pi_{\text{code, office, number}}(R2)$$

Join Example (cont'd)

You could do all of that, or you could do a join

■ Result
$$\leftarrow$$
 R \bowtie dcode = code S

Example of applying CARTESIAN PRODUCT

Binary Relational Operations: JOIN

- JOIN Operation (denoted by ⋈)
 - The sequence of CARTESIAN PRODECT followed by SELECT is used quite commonly to identify and select related tuples from two relations
 - A special operation, called JOIN combines this sequence into a single operation
 - This operation is very important for any relational database with more than a single relation, because it allows us combine related tuples from various relations
 - The general form of a join operation on two relations R(A1, A2, . . ., An) and S(B1, B2, . . ., Bm) is:

$$R \bowtie_{< join \ condition>} S$$

 where R and S can be any relations that result from general relational algebra expressions.

Binary Relational Operations: JOIN (cont.)

- Example: Suppose that we want to retrieve the name of the manager of each department.
 - To get the manager's name, we need to combine each DEPARTMENT tuple with the EMPLOYEE tuple whose SSN value matches the MGRSSN value in the department tuple.
 - We do this by using the join > operation.
 - DEPT_MGR ← DEPARTMENT MGRSSN=SSN EMPLOYEE
- MGRSSN=SSN is the join condition
 - Combines each department record with the employee who manages the department
 - The join condition can also be specified as DEPARTMENT.MGRSSN= EMPLOYEE.SSN

Types of Joins

- Left Outer Join
 - keep all of the tuples from the "left" relation
 - join with the right relation
 - pad the non-matching tuples with nulls
- Right Outer Join
 - same as the left, but keep tuples from the "right" relation
- Full Outer Join
 - same as left, but keep all tuples from both relations

Left Outer Join

	Harrio	рпопо
ם	Α	В
R=	С	D

	Harrie	Ciliali
0	Α	F
S =	G	H

- If we do a left outer join on R and S, and we match on the first column, the result is:
- Result= R → R.name=S.name S

<u>name</u>	phone	email
Α	В	F
С	D	_

Right Outer Join

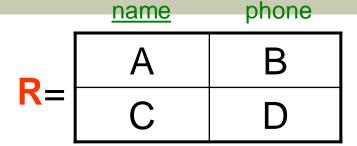

_	Harrio	priorio
ם	Α	В
R=	С	D

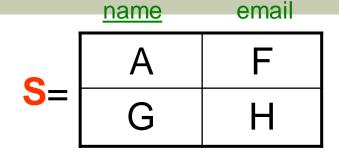

- If we do a right outer join on R and S, and we match on the first column, the result is:
- Result= R \ R.name=S.name S

name	phone	email	
А	В	F	
G	-	Н	

Full Outer Join

If we do a full outer join on R and S, and we match on the first column, the result is:

<u>name</u>	phone	email
A	В	F
С	D	-
G	-	Н

3753 X2 - 2003

Additional Relational Operations (cont.)

- The left outer join operation keeps every tuple in the first or left relation R in R ⊃S; if no matching tuple is found in S, then the attributes of S in the join result are filled or "padded" with null values.
- A similar operation, right outer join, keeps every tuple in the second or right relation S in the result of R X S.
- A third operation, full outer join, denoted by keeps all tuples in both the left and the right relations when no matching tuples are found, padding them with null values as needed.

Additional Relational Operations (cont.)

Additional Relational Operations: Aggregate Functions and Grouping

- A type of request that cannot be expressed in the basic relational algebra is to specify mathematical aggregate functions on collections of values from the database.
- Examples of such functions include retrieving the average or total salary of all employees or the total number of employee tuples.
 - These functions are used in simple statistical queries that summarize information from the database tuples.
- Common functions applied to collections of numeric values include
 - SUM, AVERAGE, MAXIMUM, and MINIMUM.
- The COUNT function is used for counting tuples or values.

Aggregate Function Operation

- Use of the Aggregate Functional operation \mathcal{F}
 - \$\mathcal{F}_{MAX Salary}\$ (EMPLOYEE) retrieves the maximum salary value from the EMPLOYEE relation
 - \$\mathcal{F}_{MIN Salary}\$ (EMPLOYEE) retrieves the minimum Salary value from the EMPLOYEE relation
 - \(\mathcal{F}_{SUM Salary}\) (EMPLOYEE) retrieves the sum of the Salary from the EMPLOYEE relation
 - $\mathcal{F}_{\text{COUNT SSN, AVERAGE Salary}}$ (EMPLOYEE) computes the count (number) of employees and their average salary
 - Note: count just counts the number of rows, without removing duplicates

Using Grouping with Aggregation

- The previous examples all summarized one or more attributes for a set of tuples
 - Maximum Salary or Count (number of) Ssn
- Grouping can be combined with Aggregate Functions
- Example: For each department, retrieve the DNO, COUNT SSN, and AVERAGE SALARY
- A variation of aggregate operation \mathcal{F} allows this:
 - Grouping attribute placed to left of symbol
 - Aggregate functions to right of symbol
 - DNO FCOUNT SSN, AVERAGE Salary (EMPLOYEE)
- Above operation groups employees by DNO (department number) and computes the count of employees and average salary per department

Examples of applying aggregate functions and grouping

Figure 6.10

The aggregate function operation.

(a) $\rho_{R(\text{Dno, No_of_employees, Average_sal})}$ (ρ_{Dno} Count Ssn, Average Salary (EMPLOYEE)). (b) ρ_{Dno} Count Ssn, Average Salary (EMPLOYEE). (c) $\rho_{\text{Count Ssn, Average Salary}}$ (EMPLOYEE).

	٠	c
_		٦

Dno	No_of_employees	Average_sal
5	4	33250
4	3	31000
1	1	55000

(b)

)	Dno	Count_ssn	Average_salary
	5	4	33250
	4	3	31000
Ě	1	1	55000

(c)

Count_ssn	Average_salary					
8	35125					

Illustrating aggregate functions and grouping

Figure 8.6 Results of GROUP BY and HAVING. (a) Q24. (b) Q26.

Fname	Minit	Lname	<u>Ssn</u>		Salary	Super_ssn	Dno			Dno	Count (*)	Avg (Salary)
John	В	Smith	123456789		30000	333445555	5]] _	-	5	4	33250
Franklin	Т	Wong	333445555		40000	888665555	5	$\prod_{i=1}^{n}$	-	4	3	31000

Grouping EMPLOYEE tuples by the value of Dno

- if we want to find the information for Regular Class and Extra Class which are conducted during morning, then, we can use the following operation:
- σ_{time = 'morning'} (RegularClass ExtraClass)
- $\Pi_{Studentname}$ ($\sigma_{time = 'morning'}$ (RegularClass $\bowtie_{Rsid=Esid}$ ExtraClass))
